新增一個 API：

PATCH /api/auth/update-name

功能：

修改 user name and verify name logic

system design

question：if an app have one million user and everyone call "Get /api/auth/me at the same time.

which's layer will gonna be "bottleneck"？

Database ⇒ cause, each request will query the database once.

The really problem is "reading speed"

that's query per second (QPS)

Solution: using "cache like Redis",

store frequently used data in memory to avoid querying the database every time.

The process will become:

Request → controller →

cache (Redis)

↓

if have data → return

↓

no data

↓

database
